

WORKFLOW

DYNAMIC AGENT

Workflow vs. Dynamic Agents

Understanding the difference between fixed automation
and AI-driven decision making

Fixed, Step-by-Step Automation

A Workflow is a pre-defined sequence of steps that execute in a fixed order. Every input follows the same path — logic is baked in, not decided at runtime.

Every execution: same path, same order — no deviation

01 Deterministic

Same input always produces the same output. No surprises.

02 Rule-Based

Logic is hard-coded in conditions, branches and scripts.

03 Predictable

Easy to audit, test and maintain in regulated environments.

LLM-Powered, Context-Aware Decision Making

A Dynamic Agent uses an LLM to reason about the situation at runtime, then picks the right tools or actions dynamically — no fixed path, no pre-written rules for every case.

Path chosen at runtime — based on context, not pre-written rules

01 Contextual

Reads the full situation before deciding what to do.

02 Tool-Using

Picks from a toolbox — search, APIs, code — as needed.

03 Adaptive

Handles novel inputs without manual rule updates.

Side by Side

Dimension	Workflow	Dynamic Agent
Logic location	Pre-coded rules	LLM decides at runtime
Flexibility	Fixed path only	Handles novel inputs
Cost	Low (no LLM)	Higher (LLM tokens)
Reliability	Fully deterministic	Varies per run
Auditability	Full step log	Reasoning less visible
Maintenance	Manual rule updates	Prompt & model updates

Use WORKFLOW when...

- Steps are known & repeatable
- Compliance/audit trail needed
- Speed & cost are priorities

Use DYNAMIC AGENT when...

- Inputs are varied or unpredictable
- Multi-tool reasoning is needed
- Flexibility outweighs consistency
